

# Evolutionary Algorithms in Convolutional Neural Network Design

Filip Badáň\*

## Abstract

Designing deep convolutional neural networks, which are nowadays successfully applied in a wide range of various fields, can be a very challenging task requiring a great deal of experience. The aim of this work is to minimize human effort needed to design convolutional neural networks and automatize the whole process of finding efficient and successful architectures. Proposed framework uses a modified version of an evolutionary algorithm, which is developed to find accurate and fully-trained convolutional neural networks to solve various image classification problems. The framework uses the so-called weight inheritance technique, which allows the training process to be considered as a special kind of mutation and by that drastically reduce time complexity of the evolution cycle. An innovative concept of the training age which gives "younger" but potentially better candidates an opportunity to succeed is also proposed. The framework has been validated on the standard image classification datasets – MNIST and CIFAR10. The initial experiments yielded fully-trained networks with almost 99% test accuracy on MNIST dataset in a relatively short evolution time. The results showed that neuroevolution has a promising potential to automatize the process of designing neural networks.

## 1. Introduction

Convolutional neural networks (CNNs) are currently successfully used in a wide range of fields such as computer vision, image classification and natural language processing [1]. For many of these application domains, very deep neural networks (i.e. networks with many hidden layers) are needed to solve the problem. Finding accurate (and possibly compact) neural network structures for solving complex problems is usually a hard task even for experienced neural network designers. It requires a significant amount of experiments and great knowledge of processed data. That is the reason, why there is growing potential for algorithms finding complex CNN architectures, which are capable of delivering the best results on a given dataset.

Evolutionary algorithms have proven to be effective in many optimization problems, for example, in hardware design [2], astronomy, robotics [3, 4] and

planning. It is therefore natural, that evolutionary algorithms have also been used to automatize the process of developing neural network structures and they have quickly become a respected method used for this task. In the literature, the connection of evolutionary computing and neural networks is often referred to as *neuroevolution*.

The current state-of-the-art work in the neuroevolution field achieved promising results and showed a big potential for automatization of a neural network design with the help of evolutionary algorithms.

The goal of this work is to design and implement a framework which can be used by CNN designers to automatically discover effective and accurate network architectures or to optimize existing but not satisfactory ones. It uses a slightly modified version of common evolutionary algorithms with some novel techniques.

The results achieved after initial experiments showed

37 that is possible to use the proposed method to de- 86  
38 sign convolutional neural networks. The best result 87  
39 achieved on MNIST dataset was 98.88% and 62.3% ac- 88  
40 curacy was achieved after the experiment on CIFAR10 89  
41 dataset. These initial results were gained with limited 90  
42 computational resources allocated and within a few 91  
43 experiments only. The detailed explanation of these 92  
44 results and future ideas how to enhance them will be 93  
45 discussed in later sections.

46 Please note, that the work is still in progress and  
47 presented results are not final. More experiments on a  
48 larger scale are required to explore the full potential of  
49 the proposed algorithm.

## 50 2. Theoretical background 95

51 This section briefly describes convolutional neural net- 96  
52 works and evolutionary algorithms, which are needed 97  
53 to understand this paper. 98

### 54 2.1 Convolutional neural networks 99

55 Convolutional neural networks are a very popular class 100  
56 of feedforward deep neural networks used for image 101  
57 classification and recognition tasks [1]. They consist 102  
58 of an input layer, an output layer and (usually) many 103  
59 hidden layers. Basic component of a CNN is a *convolu-* 104  
60 *tional layer*, whose role is to extract new features from 105  
61 an input image by the operation called *convolution*. 106  
62 The extracted features are then used by the network to 107  
63 determine an output class of an input image. Values of 108  
64 filters applied through the convolution at each convo- 109  
65 lutional layer are learned by means of training on the 110  
66 training data set. After the training process is finished, 111  
67 the network is validated on another data set – the test 112  
68 set. The second main type of CNN layers is called 113  
69 *pooling layer*. It is used for reducing the spatial size 114  
70 of an input image. A fully-connected layer is usually 115  
71 (but not necessarily) applied in the end of a CNN to 116  
72 perform the classification operation. 117

### 73 2.2 Evolutionary computing 118

74 The family of algorithms inspired by biological evolu- 119  
75 tion is uniformly called evolutionary algorithms (EA). 120  
76 The main driving force of biological evolution is the 121  
77 natural selection or, in other words – the survival of the 122  
78 fittest principle. The idea behind the natural selection 123  
79 mechanism is following: in a population of individuals 124  
80 competing for limited resources, only the best ones 125  
81 are able to survive or to reproduce. In the context of 126  
82 evolutionary algorithms, the quality of each individual 127  
83 is measured by a so called fitness function, which is 128  
84 highly dependent on the problem being solved. Every 129  
85 potential solution – phenotype – is encoded as a *geno-* 130

*type* inside an EA. Variation operators called muta- 86  
tion and crossover (recombination) are then applied to 87  
some selected genotypes to produce offspring individu- 88  
als. In order to increase the mean quality of individuals 89  
in a population, only individuals with the highest fit- 90  
ness are selected as parents or will survive to the next 91  
generation. The process of selection, recombination 92  
and evaluation is repeated until a suitable solution is 93  
discovered or the available time is exhausted. 94

## 3. Related work 95

Roots of neuroevolution date back to 80s when a sim- 96  
ple genetic algorithm evolving neural network struc- 97  
tures was introduced [5]. Since then, evolutionary 98  
computing was successfully applied not only in discov- 99  
ering architectures of neural networks but also as a 100  
promising alternative (or addition) to the backpropa- 101  
gation algorithm which is the major method used for 102  
learning of neural networks [6] [7]. While our work 103  
is concerned with evolving only structures of neural 104  
networks, this paper will focus only on this area of 105  
neuroevolution. 106

American researcher Kenneth O. Stanley intro- 107  
duced his algorithm **NEAT** (NeuroEvolution of Aug- 108  
menting Topologies) in 2002 [8]. NEAT has later 109  
grown into the foundation for many other successful 110  
applications of neuroevolution. The basic principle of 111  
NEAT algorithm is in creating nodes (neurons) and 112  
the connections between them, including their weights. 113  
This is done by a simple set of mutations and the evolu- 114  
tion process. It uses a direct encoding which means in 115  
the context of neuroevolution that every neuron is di- 116  
rectly represented by the particular gene. While NEAT 117  
works perfectly for smaller networks, it becomes very 118  
inefficient when it comes to discovering deeper ones. 119

This inefficiency was the main reason why in 2009 120  
Stanley proposed **HyperNEAT** [9] which uses a spe- 121  
cial kind of indirect encoding called Compositional 122  
Pattern Producing Networks (CPPN). CPPNs use com- 123  
plex functions to set the weights of connections be- 124  
tween two nodes. The structure of a network is partly 125  
predefined and only these functions are evolved. This 126  
allows the algorithm to be much more scalable and 127  
find more complex structures. 128

In 2017 **DeepNEAT** and **CoDeepNEAT** were pre- 129  
sented [10]. The authors of these algorithms have tried 130  
to extend the original NEAT algorithm to be able to 131  
find very deep neural networks. To achieve this, in- 132  
stead of simple neurons they encoded entire layers 133  
(together with their parameters) into a genotype. They 134  
also brought a high level of modularity into the design 135  
and were able to evolve very deep and accurate archi- 136

137 tectures which could almost compete even with the  
138 state-of-the-art architectures.

139 The first relevant work on evolution of convolutional  
140 neural networks was **Large-scale evolution of image classifiers**  
141 proposed in 2017 by Real et al [11]. They were the first to  
142 achieve results comparable to the state-of-the-art CNNs on  
143 commonly used benchmark data sets for image classification –  
144 CIFAR10 and CIFAR100. In their work they used a modified  
145 version of a genetic algorithm with a set of mutations  
146 inspired by NEAT, but customized for CNNs. Similarly to  
147 DeepNEAT they also made use of encoding of entire layers  
148 to be capable of discovering very deep architectures. The  
149 paper also presented an idea of combining classical training  
150 process with evolution via the weight inheritance. In other  
151 words, it means that every offspring can inherit learned  
152 weights from its parent every time possible.

155 The most recent work on evolving CNNs is **CNN-GA**  
156 from 2018 [12]. It utilizes the power of residual  
157 connections and modularity to surpass even the results of  
158 the **large-scale evolution** and all other neuroevolution  
159 algorithms. The basic building block of CNN-GA is a module  
160 consisting of two convolutional layers and one residual  
161 connection called *skip layer*. Another type of a building  
162 block is the pool layer module and every neural network  
163 is a combination of these modules with various parameters.  
164 Evolution of networks is realized by the genetic algorithm  
165 utilizing a special set of mutation and crossover operators.  
166 As the obtained results are remarkable – with 95.22%  
167 accuracy on CIFAR10 and 77.97% on CIFAR100 data set –  
168 this work can be considered as the current state-of-the-art  
169 in this area.

## 171 4. Neuroevolution framework

172 The goal of this framework is to build up on concepts  
173 proposed in the literature and introduce some new ideas  
174 aimed to further reduce time and computational complexity  
175 of the neuroevolution process. The main principles of the  
176 proposed framework will be described in this section.  
177 Figure 1 shows a scheme of main components of the  
178 framework and the connections between them.

180 The evolutionary algorithm works independently of  
181 used CNN library thanks to the wrapper whose objective  
182 is to map a structure of a network represented by a  
183 genotype to the internal representation of CNN in the  
184 library. The library is responsible for training and  
185 evaluating candidate solutions and saving learned  
186 parameters. Storing weights in separate files is  
187 important because of the weight inheritance which will be

described later in the text in more detail. 188

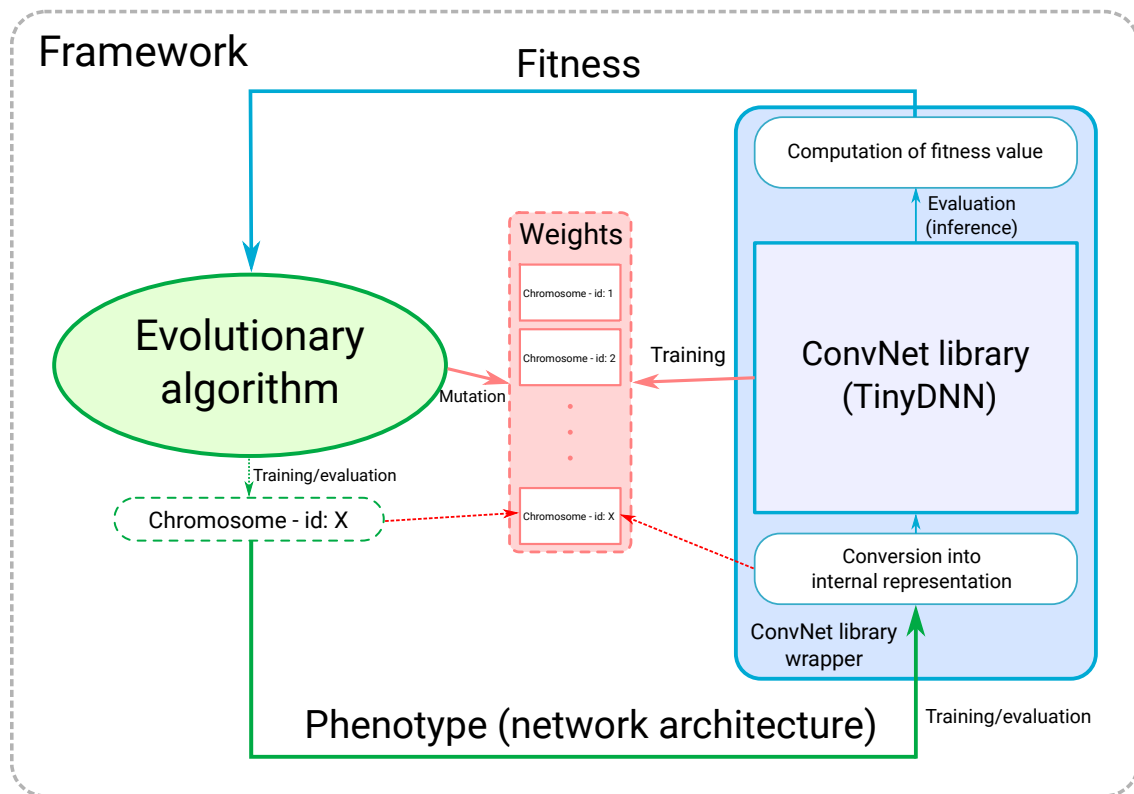

The library used for this work is called TinyDNN [13],  
which was chosen mainly because of its speed and flexibility.  
It only consists of header files and is, therefore, very compact  
and portable. It supports all common features of convolutional  
neural networks published in the literature. For optimizing the  
parameters it applies the standard backpropagation algorithm  
based on stochastic gradient descent. 196

## 5. Proposed evolutionary algorithm 197

This section will outline the most important characteristics  
of the proposed evolutionary algorithm. For now the algorithm  
uses only mutation operators which are slightly inspired by  
[11] and work as follows: 201

- **INSERT** - inserts a convolutional/pool layer on random index 202
- **REMOVE** - removes the layer on random index 203
- **ALTER** - alters the layer on random index according to the type of layer 204
- **ALTER LEARNING** - changes the learning rate 205
- **RESET** - resets the weights 206
- **TRAIN** - trains the individual for one epoch using backpropagation 207

The selection mechanism is based on modified ( $\mu + \lambda$ )  
selection where  $\mu$  is the number of parents and  $\lambda$  is the  
number of offspring. It is obvious that while the TRAIN  
mutation can raise the individual's fitness (i.e. accuracy),  
mutations like INSERT or REMOVE would almost surely  
lower it, at least until the weights are optimized again.  
It is, therefore, important to give a chance to survive  
even for more innovative but less trained individuals.  
That is the reason why the concept of *training age*,  
inspired by speciation (or niching) in NEAT algorithm,  
was introduced. While in NEAT the individuals are  
separated into species by a similarity in the structure,  
in this work the separation is done based on the  
*training age*. The training age is raised every time  
the individual undergoes a training process (via  
mutation) and lowered when some accuracy-lowering  
mutation (such as inserting or removing a convolutional  
layer) is executed. The selection mechanism then  
selects  $k$  best candidates from a group of individuals  
with the same age, where  $k$  is a random number  
between zero and a number given by the population  
size. This cycle is repeated until  $\mu$  individuals are  
selected. The entire cycle of the evolutionary algorithm  
is given in Algorithm 1. 235

**Figure 1.** Framework scheme. The evolutionary algorithm is generating genotypes (chromosomes) which are converted into the internal representation of CNN library in the library wrapper. Afterwards, the network can be trained or evaluated by the library. The accuracy achieved by the network is sent as a fitness value back to the EA. The weights are stored in separate files and can be changed by either the library or the evolutionary algorithm.

**Algorithm 1** Pseudo-code of the evolutionary cycle.

```

1: procedure EA
2:   initialize a population
3:   evaluate the initial population
4:   while CurGeneration < Generations do
5:     mutate all parents to create offspring
6:     evaluate the new individuals
7:     while individuals != population size do
8:       for every age class do
9:         get random number k from (0,n)
10:        select k best individuals
11:      end for
12:    end while
13:  end while
14: end procedure

```

- *Convolutional layer* – basic building block of convolutional neural networks; 243  
*parameters:* kernelSize, outChannels, stride and padding. 244  
245
- *Pool layer* - downsampling of the input; 247  
*parameters:* stride, poolSize and poolType. 248

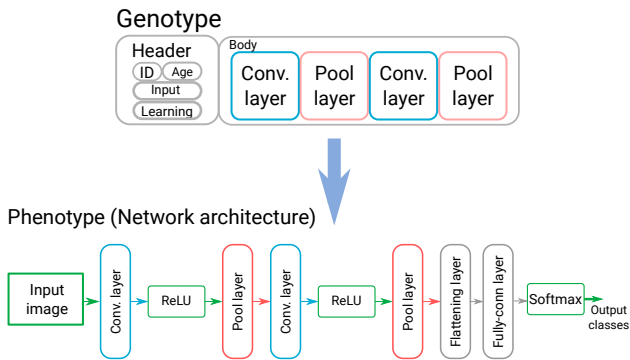

Because of the proposed straightforward encoding of candidate networks, the conversion from a genotype to the internal representation of a CNN in the CNN library is very simple. Only differences between the encoded genotype and the final representation are the activation layers which come after convolutional layers and two final layers responsible for smooth transition to the output classes. 249  
250  
251  
252  
253  
254  
255  
256

**5.2 Weight inheritance** 257

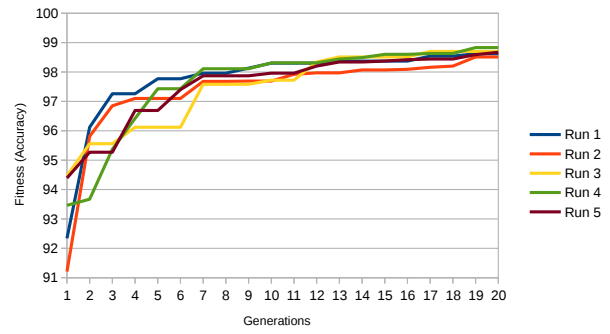

In order to reduce the time and computational complexity of the entire evolution, all learned weights are inherited from the parent to offspring as proposed in [11]. This technique is also further enhanced by preserving as many weights as possible, even in the case mutation changes shape of some layer. If there are fewer weights in the mutated network, old weights are resized and cut accordingly. Other way around, if 258  
259  
260  
261  
262  
263  
264  
265

236 **5.1 Problem encoding**

237 Encoding of a phenotype into a genotype is shown in  
 238 Figure 2. Every genotype consists of a header with  
 239 a basic information about the network represented by  
 240 the genotype and its structure (body). Structure of  
 241 the network is a combination of two different types of  
 242 layers:

**Figure 2.** Example of conversion of the genotype into the phenotype (network architecture). There is a ReLU activation behind every convolutional layer and two final layers (flattening and fully connected layer) responsible for the transition to classification classes. For the sake of simplicity the parameters which are also encoded in the chromosome are disregarded in this figure.

**Figure 3.** The progress of five independent EA runs in the task of CNN-based MNIST classifier design. The horizontal axis represents the fitness i.e. the accuracy of the best solution and the vertical axis represents the number of generation.

The average execution time is 5.53 hours on a 16-core node of the Anselm computer. It is also important to mention that the reported networks emerged only from the evolutionary process which means that the framework is able to discover accurate networks without the need of additional training. The results are promising in the context of future experiments of larger scale (i.e. bigger population and more generations) and new algorithm improvements. Additional tuning of the parameters of the EA, such as mutation probabilities, can also help to reach a higher test accuracy.

A single run of the EA on CIFAR10 data set was also conducted with the same initial CNN and the EA operating with 10 individuals in the population and 30 generations. The test accuracy reached in this experiment was 62.37% which is far from the state-of-the-art results. The reason for this is that CIFAR10 data set requires deeper networks to reach a reasonable accuracy and our experiment was executed for too short period of time. More experiments are needed to determine the ability of the framework to find such deep neural networks.

## 7. Conclusion 319

This paper introduced a new framework intended for minimizing human effort needed for designing convolutional neural networks on a specific task in the category of image classification. To achieve this it uses modified version of the evolutionary algorithm with some innovative techniques such as *training age*.

The framework was validated using a few initial experiments on the standard benchmark data sets of MNIST and CIFAR10.

### 7.1 Future work 329

While this project is still in progress, many new ideas are being worked on. There is an ongoing process

266 there is more weights in the mutated layer, the remain-  
 267 ing weights are initialized to zero by the evolutionary  
 268 algorithm.

## 269 6. Experimental results

270 All experiments were conducted on the IT4T super-  
 271 computer Anselm in Ostrava. The experimental results  
 272 described in this section are only initial and thus only  
 273 demonstrate the basic potential of the proposed algo-  
 274 rithm. More work is required to reach a higher level of  
 275 accuracy and compete with the state-of-the-art results.

276 In the first experiment, we started with a CNN with  
 277 the following parameters: one convolutional layer with  
 278 six kernels of size 5x5 and one max pooling layer with  
 279 pool size of 4. The starting learning rate was set to  
 280 0.1. The goal of the EA was to modify the topology  
 281 and find suitable weights. The weights of individual  
 282 mutations were set as follows:

- 283 • *INSERT* – 55
- 284 • *REMOVE* – 10
- 285 • *ALTER* – 15
- 286 • *ALTER LEARNING* – 5
- 287 • *RESET* – 5
- 288 • *TRAIN* – 45

289 The MNIST database was chosen as the base bench-  
 290 mark dataset because it can demonstrate the potential  
 291 of the proposed method in a short amount of time.  
 292 EA employed a relatively small population of eight  
 293 individuals and produced 20 generations in each run.

294 The results on this data set reached 98.70% test  
 295 accuracy on average from five runs and the best net-  
 296 work from all these runs reached 98.88% accuracy.

332 of tuning evolution parameters to get the best results  
333 possible. Another new feature being explored is an  
334 employment of a crossover operator which could sig-  
335 nificantly fasten up the evolution. Last but not the least,  
336 integrating residual connections which have proven to  
337 be effective in many deep CNNs could help in finding  
338 very deep neural networks architectures.

### 339 Acknowledgements

340 I would like to sincerely thank my supervisor prof. Lukas  
341 Sekanina for his help and assistance while working on  
342 this project. This work was supported by The Ministry  
343 of Education, Youth and Sports from the Large Infras-  
344 tructures for Research, Experimental Development and  
345 Innovations project „IT4Innovations National Super-  
346 computing Center – LM2015070“.
